Abstract:
• In this communication, we study doubly truncated weighted Kullback–Leibler divergence (KLD) between two nonnegative random variables. The proposed measure is a generalization of the dynamic weighted KLD introduced by Yasaei Sekeh et al. (2013). In reliability theory and survival analysis, it plays a significant role to study several aspects of a system when lifetimes fall in a time interval. It is showed that under some conditions, the proposed measure determines the distribution function uniquely. Further, characterization theorems for various lifetime distributions are proved. The effect of the monotone transformation on the proposed measure is studied. Some inequalities and bounds in terms of useful measures are obtained and finally, few applications are provided.

Key-Words:
• weighted Kullback–Leibler divergence; generalized failure rate; weighted geometric vitality function; proportional (reversed) hazard model; likelihood ratio order.

AMS Subject Classification:
• 94A17, 62E10, 62N05, 60E15.
1. INTRODUCTION

Kullback–Leibler divergence (see Kullback and Leibler, 1951) is an important measure in information theory, which has proven to be useful in reliability analysis and other related fields. It measures similarity (closeness) between two statistical distributions. To be specific, let \( X \) and \( Y \) be two nonnegative absolutely continuous random variables associated with probability density functions (pdf) \( f \) and \( g \), and cumulative distribution functions (cdf) \( F \) and \( G \), respectively. Then the KLD between \( f \) and \( g \) is given by

\[
D_{KL}(X||Y) = \int_{0}^{+\infty} f(x) \ln \left( \frac{f(x)}{g(x)} \right) dx = E_f \left( \ln \left( \frac{f(X)}{g(X)} \right) \right),
\]

where “ln” stands for the natural logarithm. We remark that \( D_{KL}(X||Y) \) is nonnegative, not symmetric in \( f \) and \( g \), zero if the distributions match exactly. It is scale invariant, that is, for two nonnegative random variables \( Z_1 = aX \) and \( Z_2 = aY \) with \( a > 0 \), we have \( D_{KL}(X||Y) = D_{KL}(Z_1||Z_2) \). Note that \( D_{KL}(X||Y) \) given by (1.1), which is a special case of Csiszar’s \( \phi \)-divergence measure can be viewed as a measure of the information loss in the fitted model relative to that in the reference model. For some recent development on KLD, we refer to Kasza and Solomon (2015) and Sankaran et al. (2016).

In recent past, there have been considerable interest to enlarge the concept of uncertainty by introducing nonnegative weight function. Belis and Guiausu (1968) first proposed the notion of (discrete) weighted entropy. It takes two kind of uncertainty into consideration. One of them is related to objective probability and other is related to utility. In analogy to Belis and Guiausu (1968), Di Crescenzo and Longobardi (2006) considered the weighted differential entropy for a nonnegative absolutely continuous random variable \( X \) as \( S^w(X) = -\int_{0}^{+\infty} xf(x) \ln f(x) dx \). It is shift dependent, though the differential entropy \( S(X) = -\int_{0}^{+\infty} f(x) \ln f(x) dx \) is not. Besides weighted differential entropy, several authors introduced and studied some other weighted information measures. In this direction, we refer to Suhov and Yasaei Sekeh (2015), Mirali et al. (2017), Nourbakhsh et al. (2016), and Rajesh et al. (2017).

Recently, based on the concept of weighted differential entropy, Yasaei Sekeh et al. (2013) considered weighted KLD as

\[
D_{KL}^w(X||Y) = \int_{0}^{+\infty} xf(x) \ln \left( \frac{f(x)}{g(x)} \right) dx = E_f \left( X \ln \left( \frac{f(X)}{g(X)} \right) \right),
\]

which takes into account the qualitative characteristic related to utility. To illustrate the importance of the weighted KLD, we consider the following example.

**Example 1.1.** Let \( X_1 \) and \( Y_1 \) be two nonnegative absolutely continuous random variables with pdfs \( f_1(x) = 2x, 0 < x < 1 \) and \( g_1(x) = 2(1 - x), 0 < x < 1, \)
respectively. We consider another random variables $X_2$ and $Y_2$ with pdfs $f_2(x) = x/2$, $0 < x < 2$ and $g_2(x) = (2 - x)/2$, $0 < x < 2$, respectively. From (1.1) we obtain $D_{KLD}(X_1 || Y_1) = 1$ and $D_{KLD}(X_2 || Y_2) = 1$. Also, from (1.2) we get $D_{KLD}^w(X_1 || Y_1) = 1$ and $D_{KLD}^w(X_2 || Y_2) = 2$. Thus, from the objective probability point of view, KLD measures are same. But, when we take the qualitative characteristics into consideration, they differ. Here, $D_{KLD}^w(X_1 || Y_1) < D_{KLD}^w(X_2 || Y_2)$.

Note that when the weight function “$x$” equals to 1, $D_{KLD}^w(X || Y)$ coincides with the standard KLD given by (1.1). Yasaee Sekeh et al. (2013) considered weighted KLD between two residual (truncated from left) lifetime distributions and two past (truncated from right) lifetime distributions. But there exist several situations in real life, where statistical data are not only truncated from left or right side, but also from both sides. When data are truncated from left and right sides, we call it as doubly truncated. Doubly truncated data play a central role in various statistical analysis of survival data. Doubly truncated failure time occurs if the failure of an individual occurs within a certain interval. In medical science, the induction time data in AIDS are doubly truncated, since HIV was unknown to us before the year 1982. Also, during a survival experiment, sometimes it is required to collect data after an engineering system starts operating and before it fails. Let $X$ denote the lifetime of a system. Then the conditional random variable $(X|x < X < y)$ is known as doubly truncated lifetime. That is, event time of an individual lies within a certain time interval $(x, y)$ is only observed. Therefore, an individual is not observed if it’s event time does not fall in this predefined interval. Hence, information on the subject outside this interval is not available to the investigator. Misagh and Yari (2012) considered doubly truncated (truncated from both sides) KLD as

\[(1.3)\quad D_{KLD}(X || Y; t_1, t_2) = \int_{t_1}^{t_2} f(x) \ln \left( \frac{f(x)}{\Delta F} \right) dx,\]

where $\Delta F = F(t_2) - F(t_1)$, $\Delta G = G(t_2) - G(t_1)$ and $(t_1, t_2) \in \mathbb{D} = \{(x, y) | F(x) < F(y) \text{ and } G(x) < G(y)\}$. In this paper, we consider doubly truncated weighted KLD between $f$ and $g$, which is given by

\[(1.4)\quad D_{KLD}^w(X || Y; t_1, t_2) = \int_{t_1}^{t_2} x \frac{f(x)}{\Delta F} \ln \left( \frac{f(x)/\Delta F}{g(x)/\Delta G} \right) dx.\]

Note that $D_{KLD}^w(X || Y; t_1, t_2)$ is a generalization of the measures considered by Yasaee Sekeh et al. (2013) in the sense that it reduces to the weighted KLD between two residual lives and two past lives, when $t_2$ tends to $+\infty$ and $t_1$ tends to 0, respectively. Mathematically,

\[\lim_{t_2 \to +\infty} D_{KLD}^w(X || Y; t_1, t_2) = \int_{t_1}^{+\infty} x \frac{f(x)}{F(t_1)} \ln \left( \frac{f(x)/F(t_1)}{g(x)/G(t_1)} \right) dx\]

and

\[\lim_{t_1 \to 0} D_{KLD}^w(X || Y; t_1, t_2) = \int_{0}^{t_2} x \frac{f(x)}{F(t_2)} \ln \left( \frac{f(x)/F(t_2)}{g(x)/G(t_2)} \right) dx.\]
The doubly truncated weighted KLD given by (1.4) may take negative values, though the doubly truncated KLD always take nonnegative values. The expression given by (1.4) measures the weighted discrepancy between two systems with lifetimes \( X \) and \( Y \), which have survived up to time \( t_1 \) and have seen to be down at time \( t_2 \). In fact, (1.4) can be used to measure divergence between two distributions having different supports. We consider the following example to illustrate this.

**Example 1.2.** Let \( X \) and \( Y \) be two nonnegative absolutely continuous random variables with pdfs 
\[
f(x) = \frac{3}{4}(2x + x^2), \quad 0 < x < 1 \quad \text{and} \quad g(x) = \frac{1}{8}(1 + 3y), \quad 0 < y < 2,
\]
respectively. As supports of the distributions are different, therefore, the expression given by (1.1) can not be used to compute the divergence between \( f \) and \( g \). In this situation, one may use (1.4) for finding divergence. In particular, 
\[
D_{wKL}^r(X || Y; 0.1, 0.5) = 0.033427 \quad \text{and} \quad D_{wKL}^r(X || Y; 0.3, 0.9) = 0.014291.
\]

Again, the doubly truncated weighted KLD given by (1.4) can be expressed in terms of the doubly truncated weighted Shannon entropy and the doubly truncated weighted inaccuracy as
\[
D_{wKL}^r(X || Y; t_1, t_2) = -S_w(X; t_1, t_2) + I_w(X || Y; t_1, t_2), \tag{1.5}
\]
where \( S_w(X; t_1, t_2) \) and \( I_w(X || Y; t_1, t_2) \) are defined in the next section.

The paper is arranged as follows. First, in Section 2, we recall some preliminary definitions. Few characterization results are proved in Section 3. Further, various lifetime distributions are characterized from the relationships among reliability measures. In Section 4, we analysis the effect of the affine transformations on the doubly truncated weighted KLD. Then, few inequalities and bounds are obtained in Section 5. Section 6 contains few examples in support of the results obtained in Section 5. Finally, some concluding remarks have been added in Section 7.

Throughout the paper, the random variables are taken to be nonnegative and absolutely continuous. The terms increasing and decreasing are used in non-strict sense. The differentiation, integration and expectation wherever used are assumed to exist.

### 2. PRELIMINARY RESULTS

In this section, we present some preliminary definitions and results which are useful for the rest of the paper. Let \( X \) and \( Y \) be two nonnegative absolutely continuous random variables with pdfs \( f \) and \( g \), and cdfs \( F \) and \( G \), respectively.
Then the generalized failure rate (GFR) functions of \((X|t_1 < X < t_2)\) and \((Y|t_1 < Y < t_2)\) are given by (see Navarro and Ruiz, 1996)

\[
(2.1) \quad h^X_1(t_1, t_2) = \frac{f(t_1)}{\Delta F}, \quad h^X_2(t_1, t_2) = \frac{f(t_2)}{\Delta F},
\]

and

\[
(2.2) \quad h^Y_1(t_1, t_2) = \frac{g(t_1)}{\Delta G}, \quad h^Y_2(t_1, t_2) = \frac{g(t_2)}{\Delta G},
\]

respectively for \((t_1, t_2) \in \mathbb{I}\). Note that when \(t_2\) tends to \(+\infty\), \(h^X_1(t_1, t_2)\) reduces to the failure rate of \(X\), and when \(t_1\) tends to zero, \(h^X_2(t_1, t_2)\) reduces to reversed failure rate of \(X\). Similarly for the random variable \(Y\). Navarro and Ruiz (1996) showed that the distribution function can be uniquely determined by GFR functions.

**Definition 2.1.** Let \(X\) be a nonnegative random variable with pdf \(f\) and cdf \(F\). Then the generalized conditional mean (GCM) of a doubly truncated random variable \((X|t_1 < X < t_2)\) is given by

\[
(2.3) \quad \mu_X(t_1, t_2) = E(X|t_1 < X < t_2) = \int_{t_1}^{t_2} \frac{x f(x)}{\Delta F} dx.
\]

For some characterizations based on (2.3), one may refer to Ruiz and Navarro (1996).

**Definition 2.2.** Let \(X\) be a nonnegative random variable with pdf \(f\) and cdf \(F\). Then the geometric vitality function for \((X|t_1 < X < t_2)\) is defined as

\[
(2.4) \quad G_X(t_1, t_2) = E(\ln X|t_1 < X < t_2) = \int_{t_1}^{t_2} \frac{\ln x f(x)}{\Delta F} dx.
\]

Note that \(G_X(t_1, t_2)\) gives the geometric mean life of \(X\) truncated at two points \(t_1\) and \(t_2\). Nair and Rajesh (2000) gave some applications of geometric vitality function. Sunoj et al. (2009) discussed few properties of this measure and showed that it determines the distribution function uniquely. The weighted version of the measure given by (2.4) is defined as follows.

**Definition 2.3.** The weighted geometric vitality function of a nonnegative random variable \(X\) with pdf \(f\) and cdf \(F\) is given by

\[
(2.5) \quad G^w_X(t_1, t_2) = E(X \ln X|t_1 < X < t_2) = \int_{t_1}^{t_2} \frac{x \ln x f(x)}{\Delta F} dx.
\]
Definition 2.4. For a nonnegative random variable $X$ with pdf $f$ and cdf $F$, the doubly truncated weighted Shannon entropy is given by

$$S^w(X; t_1, t_2) = - \int_{t_1}^{t_2} x \frac{f(x)}{\Delta F} \ln \left( \frac{f(x)}{\Delta F} \right) dx. \quad (2.6)$$

In the following we consider the definition of weighted inaccuracy measure between two doubly truncated random variables.

Definition 2.5. The doubly truncated weighted inaccuracy measure between two nonnegative random variables $X$ and $Y$ is given by

$$I^w(X||Y; t_1, t_2) = - \int_{t_1}^{t_2} x \frac{f(x)}{\Delta F} \ln \left( \frac{g(x)}{\Delta G} \right) dx. \quad (2.7)$$

Next we recall the following important definition from Shaked and Shan-thikumar (2007).

Definition 2.6. Let $X$ and $Y$ be two random variables with pdfs $f$ and $g$, and cdfs $F$ and $G$, respectively. We say that $X$ is larger than $Y$ in likelihood ratio order, denoted by $X \geq_{lr} Y$ if $f(x)/g(x)$ is increasing in $x$.

Log-sum inequality: Let $m$ be a sigma finite measure. If $f$ and $g$ are positive and $m$ integrable, then

$$\int f \log \left( \frac{f}{g} \right) dm \geq \left[ \int f dm \right] \log \left[ \frac{\int f dm}{\int g dm} \right]. \quad (2.8)$$

3. CHARACTERIZATIONS

In this section, we obtain some characterization results which may be used to describe probability distributions. The general characterization problem is to determine when the doubly truncated weighted KLD uniquely determines the distribution function. Yasaei Sekeh et al. (2013) showed that under some conditions, the weighted KLD for two residual and past lifetime distributions characterizes the distribution function uniquely. In the following theorem, we show that using relationship between doubly truncated weighted KLD and GCM, and under the condition on GFR functions, one can characterize one of the distributions when other is known.

Theorem 3.1. Let $X$ and $Y$ be two absolutely continuous nonnegative random variables with pdfs $f$ and $g$ and cdfs $F$ and $G$, respectively, such that
\( h_Y^i(t_1, t_2) \leq h_X^i(t_1, t_2), i = 1, 2 \). Then the doubly truncated weighted KLD given by (1.4) characterizes the distribution function \( G \) (or \( F \)), when \( F \) (or \( G \)) is known, provided \( D_{KL}^w(X \| Y; t_1, t_2) = \mu_X(t_1, t_2) \).

**Proof:** Differentiating (1.4) partially with respect to \( t_1 \) (for any fixed \( t_2 \)) and \( t_2 \) (for any fixed \( t_1 \)), we get after simplification

\[
\frac{\partial D_{KL}^w(X \| Y; t_1, t_2)}{\partial t_1} = h_1^X(t_1, t_2) \left[ D_{KL}^w(X \| Y; t_1, t_2) + \mu_X(t_1, t_2) \right] + t_1 \ln \left( \frac{h_1^Y(t_1, t_2)}{h_1^X(t_1, t_2)} \right) - h_1^Y(t_1, t_2) \mu_X(t_1, t_2)
\]

(3.1)

and

\[
\frac{\partial D_{KL}^w(X \| Y; t_1, t_2)}{\partial t_2} = -h_2^X(t_1, t_2) \left[ D_{KL}^w(X \| Y; t_1, t_2) + \mu_X(t_1, t_2) \right] + t_2 \ln \left( \frac{h_2^Y(t_1, t_2)}{h_2^X(t_1, t_2)} \right) + h_2^Y(t_1, t_2) \mu_X(t_1, t_2).
\]

(3.2)

Moreover, differentiating (2.3) with respect to \( t_1 \) and \( t_2 \), we obtain

\[
\frac{\partial \mu_X(t_1, t_2)}{\partial t_1} = h_1^X(t_1, t_2) \left[ \mu_X(t_1, t_2) - t_1 \right]
\]

(3.3)

and

\[
\frac{\partial \mu_X(t_1, t_2)}{\partial t_2} = -h_2^X(t_1, t_2) \left[ \mu_X(t_1, t_2) - t_2 \right],
\]

(3.4)

respectively. Again, differentiating \( D_{KL}^w(X \| Y; t_1, t_2) = \mu_X(t_1, t_2) \) with respect to \( t_i \) (for fixed \( t_j, j \neq i \)), \( i, j = 1, 2 \) and using (3.1), (3.2), (3.3) and (3.4) we get

\[
t_i h_i^X(t_1, t_2) \left[ 1 + \ln \left( \frac{h_i^Y(t_1, t_2)}{h_i^X(t_1, t_2)} \right) \right] + [h_i^X(t_1, t_2) - h_i^Y(t_1, t_2)] \mu_X(t_1, t_2) = 0.
\]

(3.5)

The above equation given by (3.5) can be further written as

\[
g_i(x) = t_i [1 + \ln x] + (1 - x) \mu_X(t_1, t_2) = 0, \quad i = 1, 2,
\]

(3.6)

where \( x = h_i^Y(t_1, t_2)/h_i^X(t_1, t_2) \) and 0 < \( x < 1 \). Thus, for any fixed \( t_2 \) and arbitrary \( t_1 \), \( h_1^Y(t_1, t_2)/h_1^X(t_1, t_2) \) is a positive solution of the equation \( g_1(x) = 0 \). Also, for any fixed \( t_1 \) and arbitrary \( t_2 \), \( h_2^Y(t_1, t_2)/h_2^X(t_1, t_2) \) is a positive solution of the equation \( g_2(x) = 0 \). After some simple calculations, it is easy to show that both the solutions of \( g_1(x) = 0 \) and \( g_2(x) = 0 \) are unique. Hence, using the result that GFR functions uniquely determine the distribution function (see Navarro and Ruiz, 1996), the proof follows. This completes the proof of the theorem. □
Theorem 3.2. Let $X$ and $Y$ be two absolutely continuous nonnegative random variables with pdfs $f$ and $g$ and cdfs $F$ and $G$, respectively. Assume $h_1^Y(t_1, t_2) = \theta h_1^X(t_1, t_2)$ and $D_{KL}^w(X||Y; t_1, t_2) > (<) (\theta - 1) \mu_X(t_1, t_2) - t_1 \ln \theta$, where $\theta > 0$. If $D_{KL}^w(X||Y; t_1, t_2)$ is strictly increasing (decreasing) in $t_1$ for fixed $t_2$, then $D_{KL}^w(X||Y; t_1, t_2)$ characterizes the distribution function uniquely.

Proof: Under the given hypothesis, (3.1) is reduced to
\[
\frac{\partial D_{KL}^w(X||Y; t_1, t_2)}{\partial t_1} = h_1^X(t_1, t_2) \left[ D_{KL}^w(X||Y; t_1, t_2) + (1 - \theta) \mu_X(t_1, t_2) + t_1 \ln \theta \right].
\]
(3.7)

The expression in (3.7) can be written further as
\[
u(x) = \frac{\partial D_{KL}^w(X||Y; t_1, t_2)}{\partial t_1} - x \left[ D_{KL}^w(X||Y; t_1, t_2) + (1 - \theta) \mu_X(t_1, t_2) + t_1 \ln \theta \right]
\]
(3.8)
\[
= 0,
\]
where $x = h_1^X(t_1, t_2)$ is a positive solution of $\nu(x) = 0$. Since $D_{KL}^w(X||Y; t_1, t_2) > (<)(\theta - 1) \mu_X(t_1, t_2) - t_1 \ln \theta$, therefore from (3.8) it is easy to show that
\[
\lim_{x \to +\infty} \nu(x) = -\infty (+\infty).
\]
(3.9)

Again, $D_{KL}^w(X||Y; t_1, t_2)$ is strictly increasing (decreasing) in $t_1$ for fixed $t_2$. Therefore,
\[
\lim_{x \to -0} \nu(x) = \frac{\partial D_{KL}^w(X||Y; t_1, t_2)}{\partial t_1} > (<)0.
\]
(3.10)

Differentiating (3.8) with respect to $x$ we have $\nu'(x) = -[D_{KL}^w(X||Y; t_1, t_2) + (1 - \theta) \mu_X(t_1, t_2) + t_1 \ln \theta] < (>) 0$ implies $\nu(x)$ is a decreasing (increasing) function in $x > 0$. Hence, $x = h_1^X(t_1, t_2)$ is the only solution of $\nu(x) = 0$. This completes the proof of the theorem.

Theorem 3.3. Let $X$ and $Y$ be two absolutely continuous nonnegative random variables with pdfs $f$ and $g$ and cdfs $F$ and $G$, respectively. Assume that for $\theta > 0$, $h_2^Y(t_1, t_2) = \theta h_2^X(t_1, t_2)$ and $D_{KL}^w(X||Y; t_1, t_2) < (>)(\theta - 1) \mu_X(t_1, t_2) - t_2 \ln \theta$. If $D_{KL}^w(X||Y; t_1, t_2)$ is strictly increasing (decreasing) in $t_2$ for fixed $t_1$, then $D_{KL}^w(X||Y; t_1, t_2)$ characterizes the distribution function uniquely.

Proof: Proof follows along the similar arguments of that of the Theorem 3.2. Hence it is omitted.
It is noted that the conditions used in the above theorems are sufficient. Henceforth, we present characterization theorems for some useful continuous distributions. Let \( X \) and \( Y \) be two nonnegative absolutely continuous random variables with cdfs \( F \) and \( G \), pdfs \( f \) and \( g \), hazard rate functions \( \lambda_F \) and \( \lambda_G \) and reversed hazard rate functions \( r_F \) and \( r_G \), respectively. Then \( X \) and \( Y \) are said to satisfy the proportional hazard rate model (PHRM) and proportional reversed hazard rate model (PRHRM) if for some \( \theta > 0 \),

\[
\bar{G}(x) = [\bar{F}(x)]^\theta \quad \text{and} \quad G(x) = [F(x)]^\theta,
\]

respectively, where \( \bar{F} = 1 - F \) and \( \bar{G} = 1 - G \). The constant \( \theta \) is known as proportionality constant. Several researchers used PHRM for survival data analysis. See, for instance, Cox (1972), Ebrahimi and Kirmani (1996) and Nair and Gupta (2007). On the other hand, for various results on PRHRM, we refer to Gupta and Gupta (2007) and Sankaran and Gleeja (2008). In the following consecutive theorems, we present characterizations of the first and second kind Pareto distributions.

**Theorem 3.4.** Let \( X \) and \( Y \) be two absolutely continuous nonnegative random variables with pdfs \( f \) and \( g \) and cdfs \( F \) and \( G \), respectively. Assume that \( F \) and \( G \) satisfies PHRM with proportionality constant \( \theta > 0 \). Then for \( i = 1, 2 \), the following relationship of the form

\[
D_{KL}^\mu(X||Y; t_1, t_2) + \mu_X(t_1, t_2) \left[ \ln f(t_i) + (1 + \alpha \theta) \ln t_i + \ln \left( \frac{h_Y(t_1, t_2)}{h_X(t_1, t_2)} \right) \right]
\]

\[
= (1 + \alpha \theta) G_X(t_1, t_2) + \mu_X(t_1, t_2) \left[ \ln f(t_i) + (1 + \alpha \theta) \ln t_i + \ln \left( \frac{f(t_i)}{\Delta G} \right) - \ln \left( \frac{g(t_i)}{\Delta F} \right) \right]
\]

holds if and only if \( X \) follows Pareto-I distribution with cdf \( F(x) = 1 - (\beta/x)^\alpha \), \( x > \beta > 0, \alpha > 0 \).

**Proof:** The “if part” can be proved easily. To prove the “only if part”, we assume that (3.12) holds. Using (1.4) and after simplification, we get from (3.12)

\[
\int_{t_1}^{t_2} x f(x) \ln \left( \frac{f(x)/\Delta F}{g(x)/\Delta G} \right) dx + \left[ \ln f(t_i) + (1 + \alpha \theta) \ln t_i + \ln \left( \frac{g(t_i)}{\Delta G} \right) - \ln \left( \frac{f(t_i)}{\Delta F} \right) \right]
\]

\[
\times \int_{t_1}^{t_2} x f(x) dx = (1 + \alpha \theta) \int_{t_1}^{t_2} x f(x) \ln x dx + \int_{t_1}^{t_2} x f(x) \ln f(x) dx.
\]

Differentiating (3.13) with respect to \( t_i \) and then further calculations lead to

\[
g(t_i) = k t_i^{-(\alpha \theta + 1)} \quad \text{for} \quad i = 1, 2 \quad \text{and} \quad k > 0.
\]

Hence the required result follows. This completes the proof. □
Theorem 3.5. Let $X$ and $Y$ be two absolutely continuous random variables as described in Theorem 3.4 and satisfying PHRM with proportionality constant $\theta > 0$. Then for $i = 1, 2$, the following relationship of the form

$$D_{KL}^{w}(X||Y; t_1, t_2) + \mu_X(t_1, t_2) \left[ \ln f(t_i) + (1 + \alpha \theta) \ln(t_i - \gamma + \beta) + \ln \left( \frac{h_i^Y(t_1, t_2)}{h_i^X(t_1, t_2)} \right) \right]$$

(3.14)

$$= (1 + \alpha \theta)G_w^Z(t_1, t_2) + E(X \ln f(X)|t_1 < X < t_2),$$

where $G_w^Z(t_1, t_2) = E(X \ln(X - \gamma + \beta)|t_1 < X < t_2)$ holds if and only if $X$ follows Pareto-II distribution with cdf $F(x) = 1 - [1 + (\frac{x - \gamma}{\beta})]^{-\alpha}$, $x > \gamma > 0$, $\alpha, \beta > 0$.

Proof: The “if part” is straightforward and hence omitted. To prove the “only if part”, let us assume that (3.14) holds. Then from (3.14) and (1.4) we obtain

$$\int_{t_1}^{t_2} x f(x) \ln \left( \frac{f(x)/\Delta F}{g(x)/\Delta G} \right) dx + \left[ \ln f(t_i) + (1 + \alpha \theta) \ln(t_i - \gamma + \beta) + \ln \left( \frac{g(t_i)}{\Delta G} \right) \right]$$

$$- \ln \left( \frac{f(t_i)}{\Delta F} \right) \int_{t_1}^{t_2} x f(x) dx = (1 + \alpha \theta) \int_{t_1}^{t_2} x f(x) \ln(x - \gamma + \beta) dx$$

$$+ \int_{t_1}^{t_2} x f(x) \ln f(x) dx.$$

Differentiating (3.15) with respect to $t_i, i = 1, 2$ and after some algebraic calculations, we get

$$g(t_i) = k(t_i - \gamma + \beta)^{(1+\alpha \theta)}, i = 1, 2 \text{ and } k > 0.$$

Hence the result follows. This completes the proof of the theorem. \qed

Here, below we present a characterization theorem for Weibull distribution.

Theorem 3.6. Let $X$ and $Y$ be two absolutely continuous nonnegative random variables as mentioned in Theorem 3.4. Also, assume that they satisfy PHRM with proportionality constant $\theta > 0$. Then the following relationship of the form

$$D_{KL}^{w}(X||Y; t_1, t_2) + \mu_X(t_1, t_2) \left[ \lambda \theta \theta^p_t + \ln f(t_i) + (1 - p) \ln t_i + \ln \left( \frac{h_i^Y(t_1, t_2)}{h_i^X(t_1, t_2)} \right) \right]$$

(3.16)

$$+ \lambda \theta \mu_{X^{\lambda+1}}(t_1, t_2) = (1 - p)G_w^Z(t_1, t_2) + E(X \ln f(X)|t_1 < X < t_2), \ i = 1, 2,$$

where $\mu_{X^{\lambda+1}}(t_1, t_2) = E(X^{\lambda+1}||t_1 < X < t_2)$ and $G_w^Z(t_1, t_2) = E(X \ln(X - \gamma)|t_1 < X < t_2)$ holds if and only if $X$ follows Weibull distribution with cdf $F(x) = 1 - \exp(-\lambda x^p)$, $x > 0, p > 0, \lambda > 0$. 
Proof: The “if part” is straightforward. To prove the “only if part”, we first assume that (3.16) holds. Then using (1.4) in (3.16), we get
\[
\int_{t_1}^{t_2} xf(x) \ln \left( \frac{f(x)}{g(x)/\Delta F} \right) dx + \left[ \lambda \theta t_i^p + \ln f(t_i) + (1-p) \ln t_i + \ln \left( \frac{g(t_i)}{\Delta G} \right) \right] \int_{t_1}^{t_2} x f(x) dx = (1-p) \int_{t_1}^{t_2} x f(x) \ln(x-\alpha) dx
\]
(3.17)
\[+ \int_{t_1}^{t_2} x f(x) \ln f(x) dx - \lambda \theta \int_{t_1}^{t_2} x^{p+1} f(x) dx.\]
Differentiating (3.17) with respect to \( t_i \), \( i = 1, 2 \), and after some algebraic calculations, we obtain
\[g(t_i) = c t_i^{(p-1)} e^{-\lambda \theta t_i^p}, \quad i = 1, 2 \text{ and } c > 0.\]
Hence the required result follows. This completes the proof. \( \square \)

Remark 3.1. In particular, for \( p = 1, 2 \), the Theorem 3.6 provides characterization results of exponential distribution with cdf \( F(x) = 1 - e^{-\lambda x}, x > 0, \lambda > 0 \) and Rayleigh distribution with cdf \( F(x) = 1 - e^{-\lambda x^2}, x > 0, \lambda > 0 \), respectively.

Hereafter, we present results which characterize uniform and power distributions.

Theorem 3.7. Let \( X \) and \( Y \) be two absolutely continuous nonnegative random variables as described in Theorem 3.4 and satisfying PRHRM with proportionality constant \( \theta > 0 \). Then the following relationship of the form
\[D_{KL}^w(X||Y; t_1, t_2) + \mu_X(t_1, t_2) \left[ \ln f(t_i) + (1-\theta) \ln(t_i-\alpha) + \ln \left( \frac{\mu_Y(t_1, t_2)}{\mu_X(t_1, t_2)} \right) \right]
\]
(3.18)
\[= (1-\theta)G_{\alpha, \beta}^w(t_1, t_2) + E(X \ln f(X) | t_1 < X < t_2), \quad i = 1, 2,\]
where \( G_{\alpha, \beta}^w(t_1, t_2) = E(X \ln(X-\alpha) | t_1 < X < t_2) \) and \( \alpha < t_1 < t_2 < \beta \) holds if and only if \( X \) follows uniform distribution in the interval \((\alpha, \beta)\).

Proof: The “if part” is straightforward. To prove the “only if part”, assume that (3.18) holds for \( i = 1 \) and 2. Using (1.4), the above relation (3.18) further reduces to
\[
\int_{t_1}^{t_2} xf(x) \ln \left( \frac{f(x)}{g(x)/\Delta F} \right) dx + \left[ \ln f(t_i) + (1-\theta) \ln(t_i-\alpha) + \ln \left( \frac{g(t_i)}{\Delta G} \right) \right] \int_{t_1}^{t_2} x f(x) dx = (1-\theta) \int_{t_1}^{t_2} x f(x) \ln(x-\alpha) dx
\]
(3.19)
\[- \ln \left( \frac{f(t_i)}{\Delta F} \right) \int_{t_1}^{t_2} x f(x) dx + \int_{t_1}^{t_2} x f(x) \ln f(x) dx,
\]
...
for $i = 1, 2$. Differentiating (3.19) with respect to $t_i$, $i = 1, 2$ and then simplifying further, we obtain

$$g(t_i) = c(t_i - \alpha)^{(\theta - 1)}, \quad i = 1, 2 \text{ and } c > 0,$$

which gives the required result. This completes the proof.

**Theorem 3.8.** Let $X$ and $Y$ be two absolutely continuous nonnegative random variables as mentioned in Theorem 3.4 and satisfying PRHRM with proportionality constant $\theta > 0$. Then for $c > 0$, the following relationship of the form

$$D_{wKL}(X||Y; t_1, t_2) + \mu_X(t_1, t_2) \left[ \ln f(t_i) + (1 - c\theta) \ln t_i + \ln \left( \frac{h_Y(t_1, t_2)}{h_X(t_1, t_2)} \right) \right]$$

(3.20)

$$= (1 - c\theta) G_w^w_X(t_1, t_2) + E(X \ln f(X)|t_1 < X < t_2), \quad i = 1, 2,$$

where $G_w^w_X(t_1, t_2)$ is given by (2.5) holds if and only if $X$ follows power distribution with cdf $F(x) = \left( \frac{x}{b} \right)^c$, $0 < x < b, c > 0$.

**Proof:** The “if part” is straightforward. To prove the “only if part”, let us assume that (3.20) holds. Using (1.4), (3.20) further reduces to

$$\int_{t_1}^{t_2} x f(x) \ln \left( \frac{f(x)/\Delta F}{g(x)/\Delta G} \right) dx + \left[ \ln f(t_i) + (1 - c\theta) \ln t_i + \ln \left( \frac{g(t_i)}{\Delta G} \right) - \ln \left( \frac{f(t_i)}{\Delta F} \right) \right]$$

(3.21)

$$\times \int_{t_1}^{t_2} x f(x) dx = (1 - c\theta) \int_{t_1}^{t_2} x f(x) \ln x dx + \int_{t_1}^{t_2} x f(x) \ln f(x) dx.$$

Differentiating (3.21) with respect to $t_i, \quad i = 1, 2$, we get

$$g(t_i) = kt_i^{(c\theta - 1)}, \quad i = 1, 2 \text{ and } k > 0,$$

which follows the required result. This completes the proof.

4. **MONOTONE TRANSFORMATIONS**

In this section, we analysis the effect of the doubly truncated weighted KLD given by (1.4) under strictly monotone transformations. The following theorem is a generalization of the Theorem 4.13 of Yasaee Sekeh et al. (2013).

**Theorem 4.1.** Let $X$ and $Y$ be two absolutely continuous nonnegative random variables with pdfs $f$ and $g$, and cdfs $F$ and $G$, respectively. Consider
two bijective functions \( \phi_1 \) and \( \phi_2 \), which are strictly monotone and differentiable. Then for all \( 0 \leq t_1 < t_2 < +\infty \), we have

\[
D_{KL}^{\psi}(\phi_1(X)||\phi_2(Y); t_1, t_2) = \begin{cases} 
D_{KL}^{\psi,\phi_1}(X||\phi_1^{-1}(\phi_2(Y)); \phi_1^{-1}(t_1), \phi_1^{-1}(t_2)), & \text{if } \phi_1 \text{ and } \phi_2 \text{ are strictly increasing,} \\
D_{KL}^{\psi,\phi_1}(X||\phi_1^{-1}(\phi_2(Y)); \phi_1^{-1}(t_2), \phi_1^{-1}(t_1)), & \text{if } \phi_1 \text{ and } \phi_2 \text{ are strictly decreasing,}
\end{cases}
\]

where

\[
D_{KL}^{\psi,\phi_1}(X||\phi_1^{-1}(\phi_2(Y)); t_1, t_2) = \int_{t_1}^{t_2} \phi(x) \frac{f(x)}{\Delta F} \ln \left( \frac{f(x)/\Delta F}{g(x)/\Delta G} \right) dx.
\]

**Proof:** Assume that \( \phi_1(x) \) and \( \phi_2(x) \) are strictly increasing functions. Under this condition, the pdfs and cdfs of \( \phi_1(X) \) and \( \phi_2(Y) \) can be obtained as

\[
f_{\phi_1}(x) = \frac{f(\phi_1^{-1}(x))}{\phi_1'(\phi_1^{-1}(x))} \quad \text{and} \quad F_{\phi_1}(x) = F(\phi_1^{-1}(x))
\]

and

\[
g_{\phi_2}(x) = \frac{f(\phi_2^{-1}(x))}{\phi_2'(\phi_2^{-1}(x))} \quad \text{and} \quad G_{\phi_2}(x) = G(\phi_2^{-1}(x)),
\]

respectively. Moreover, the pdf and the cdf of \( \phi_1^{-1}(\phi_2(X)) \) are respectively given by

\[
g_{\phi_1^{-1}(\phi_2)}(x) = \frac{g(\phi_2^{-1}(\phi_1(x))) \phi_2'(\phi_1(x))}{\phi_2'(\phi_2^{-1}(\phi_1(x)))} \quad \text{and} \quad G_{\phi_1^{-1}(\phi_2)}(x) = G(\phi_2^{-1}(\phi_1(x))).
\]

Applying (4.2) and (4.3) in (1.4), we obtain

\[
D_{KL}^{\psi,\phi_1}(X||\phi_2(Y); t_1, t_2) = \int_{t_1}^{t_2} x f(\phi_1^{-1}(x))/\phi_1'(\phi_1^{-1}(x)) \\
\times \ln \left( \frac{f(\phi_1^{-1}(x))/\phi_1'(\phi_1^{-1}(x)) \Delta F_{\phi_1}}{g(\phi_2^{-1}(x))/\phi_2'(\phi_2^{-1}(x)) \Delta G_{\phi_2}} \right) dx,
\]

where \( \Delta F_{\phi_1} = F(\phi_1^{-1}(t_2)) - F(\phi_1^{-1}(t_1)) \) and \( \Delta G_{\phi_2} = G(\phi_2^{-1}(t_2)) - G(\phi_2^{-1}(t_1)) \).

Further, using the transformation \( u = \phi_1^{-1}(x) \) in (4.5), we get

\[
D_{KL}^{\psi,\phi_1}(X||\phi_2(Y); t_1, t_2) = \int_{\phi_1^{-1}(t_1)}^{\phi_1^{-1}(t_2)} \phi_1(u) f(u)/\Delta F_{\phi_1} \\
\times \ln \left( \frac{f(u)/\phi_1'(u) \Delta F_{\phi_1}}{g(\phi_2^{-1}(\phi_1(u)))/\phi_2'(\phi_2^{-1}(\phi_1(u))) \Delta G_{\phi_2}} \right) du.
\]

Hence from (4.6), the first part of the theorem follows. The second part can be proved similarly and hence omitted. This completes the proof of the theorem. \( \square \)
Remark 4.1. Note that when $t_1 \to 0$ (for fixed $t_2$) and $t_2 \to \infty$ (for fixed $t_1$), Theorem 4.1 reduces to Theorem 4.13 of Yasaei Sekeh et al. (2013).

Remark 4.2. Consider $\phi_1(x) = F(x)$ and $\phi_2(x) = G(x)$. Here, both $F(x)$ and $G(x)$ are strictly increasing in their supports. Also, consider $\phi_1(x) = \overline{F}(x)$ and $\phi_2(x) = \overline{G}(x)$, which are strictly decreasing in supports. Clearly, $\phi_1(x)$ and $\phi_2(x)$ satisfy the assumptions of Theorem 4.1. Thus as an application of Theorem 4.1, we get

$$D_{KL}^w(F(X)||G(Y); t_1, t_2) = D_{KL}^{w,F}(X||F^{-1}(G(Y)); F^{-1}(t_1), F^{-1}(t_2))$$

and

$$D_{KL}^w(\overline{F}(X)||\overline{G}(Y); t_1, t_2) = D_{KL}^{w,\overline{F}}(X||\overline{F}^{-1}(\overline{G}(Y)); \overline{F}^{-1}(t_2), \overline{F}^{-1}(t_1)).$$

The following proposition is due to Theorem 4.1. It provides the effects of the doubly truncated weighted KLD under affine transformations.

Proposition 4.1. Let $X$ and $Y$ be two nonnegative absolutely continuous random variables with pdfs $f$ and $g$, and cdfs $F$ and $G$, respectively. Define $\phi_1(X) = a_1X + b_1$ and $\phi_2(Y) = a_2Y + b_2$, where $a_1, a_2 > 0$ and $b_1, b_2 \geq 0$ are constants. Then for $t_1 > b_2$ and $b_2 \geq b_1$,

$$(4.9) \ D_{KL}^w(\phi_1(X)||\phi_2(Y); t_1, t_2) = D_{KL}^{w,\phi_1}(X||\frac{a_2}{a_1}Y + \frac{b_2 - b_1}{a_1} + \frac{t_1 - b_1}{a_1}, \frac{t_2 - b_1}{a_1}).$$

Remark 4.3. Under the assumptions as described in Proposition 4.1, the right hand side expression given by (4.9) can be written further as

$$D_{KL}^w(\phi_1(X)||\phi_2(Y); t_1, t_2) = a_1D_{KL}^w(X||\frac{a_2}{a_1}Y + \frac{b_2 - b_1}{a_1} + \frac{t_1 - b_1}{a_1}, \frac{t_2 - b_1}{a_1})$$

$$+ b_1D_{KL}(X||\frac{a_2}{a_1}Y + \frac{b_2 - b_1}{a_1} + \frac{t_1 - b_1}{a_1}, \frac{t_2 - b_1}{a_1}).$$

(4.10)

In particular, if we consider $\phi_1(x) = \phi_2(x) = \phi(x)$, then Theorem 4.1 reduces to the following result. We omit the proof as it follows from that of the Theorem 4.1.

Theorem 4.2. Let $X$ and $Y$ be two absolutely continuous nonnegative random variables as described in Theorem 4.1. Assume that $\phi(x)$ is strictly monotone and differentiable function. Then for all $0 \leq t_1 < t_2 < +\infty$, we have

$$D_{KL}^w(\phi(X)||\phi(Y); t_1, t_2) = \begin{cases} D_{KL}^{w,\phi}(X||Y; \phi^{-1}(t_1), \phi^{-1}(t_2)), \\
D_{KL}^{w,\phi}(X||Y; \phi^{-1}(t_2), \phi^{-1}(t_1)), \end{cases}$$

where $D_{KL}^{w,\phi}(X||Y; t_1, t_2)$ is given by (4.1).
Proposition 4.2. Let $X$ and $Y$ be two nonnegative absolutely continuous random variables with pdfs $f$ and $g$, and cdfs $F$ and $G$, respectively. Define $\phi_1(x) = \phi_2(x) = \phi(x) = ax + b$, where $a > 0$ and $b \geq 0$ are constants. Then for $t_1 > b$

\begin{equation}
D_{KL}^w(\phi(X)||\phi(Y); t_1, t_2) = D_{KL}^w(X||Y; \frac{t_1 - b}{a}, \frac{t_2 - b}{a}).
\end{equation}

5. INEQUALITIES AND BOUNDS

In this section, we obtain various inequalities and bounds for doubly truncated weighted KLD given by (1.4) in terms of other measures, which may be useful in mathematical statistics, ergodic theory and other scientific fields. Most of these depend on the measures (2.1)–(2.3) and (2.5)–(2.7). Several authors studied these measures and obtained various results. For some results on these measures, we refer to Navarro and Ruiz (1996), Misagh and Yari (2011), Sankaran and Sunoj (2004) and Kundu (2017).

Proposition 5.1. Let $X$ and $Y$ be two nonnegative absolutely continuous random variables with pdfs $f$ and $g$, and cdfs $F$ and $G$, respectively. Suppose that $D_{KL}^w(X||Y; t_1, t_2)$ is increasing (decreasing) in $t_1$ (for fixed $t_2$) and $t_2$ (for fixed $t_1$). Then

\begin{align*}
D_{KL}^w(X||Y; t_1, t_2) &\geq (\leq) \left( \frac{h_Y^1(t_1, t_2)}{h_X^1(t_1, t_2)} - 1 \right) \mu_X(t_1, t_2) - t_1 \ln \left( \frac{h_Y^1(t_1, t_2)}{h_X^1(t_1, t_2)} \right) \\
&\text{and} \\
D_{KL}^w(X||Y; t_1, t_2) &\leq (\geq) \left( \frac{h_Y^2(t_1, t_2)}{h_X^2(t_1, t_2)} - 1 \right) \mu_X(t_1, t_2) - t_2 \ln \left( \frac{h_Y^2(t_1, t_2)}{h_X^2(t_1, t_2)} \right).
\end{align*}

Proof: Under the given condition, the required inequalities follow from (3.1) and (3.2), and hence, omitted.

The following proposition provides bounds of (1.4) in terms of GCM, GFR functions and doubly truncated weighted inaccuracy measure.

Proposition 5.2. Let $X$ and $Y$ be two random variables as described in Proposition 5.1. If $f(x)$ is increasing (decreasing) in $x > 0$, then

\begin{align*}
D_{KL}^w(X||Y; t_1, t_2) &\geq (\leq) \mu_X(t_1, t_2) \ln h_X^1(t_1, t_2) + I^w(X||Y; t_1, t_2) \\
&\text{and} \\
D_{KL}^w(X||Y; t_1, t_2) &\leq (\geq) \mu_X(t_1, t_2) \ln h_X^2(t_1, t_2) + I^w(X||Y; t_1, t_2).
\end{align*}
Multiplying (5.3) by \( f(x) \) and then integrating from \( t_1 \) to \( t_2 \) with respect to \( x \), the required inequalities follow.

**Proposition 5.3.** Let \( X \) and \( Y \) be two random variables as described in Proposition 5.1. If \( g(x) \) is increasing (decreasing) in \( x > 0 \), then

\[
D_{KL}^w(X[Y; t_1, t_2]) \geq (\leq) -\mu_X(t_1, t_2) \ln h_Y^X(t_1, t_2) - S_X^Y(t_1, t_2)
\]

and

\[
D_{KL}^w(X[Y; t_1, t_2]) \leq (\geq) -\mu_X(t_1, t_2) \ln h_Y^X(t_1, t_2) - S_X^Y(t_1, t_2).
\]

**Proof:** Proof follows analogous to that of the Proposition 5.2. Hence omitted.

Below, in Proposition 5.4, we give new inequalities for \( D_{KL}^w(X[Y; t_1, t_2]) \) involving a pair of likelihood ratio ordered random variables.

**Proposition 5.4.** Let \( X \) and \( Y \) be two random variables as described in Proposition 5.1. If \( X \geq_{lr} Y \), then

\[
\mu_X(t_1, t_2) \ln \left( \frac{h_X^X(t_1, t_2)}{h_Y^X(t_1, t_2)} \right) \leq D_{KL}^w(X[Y; t_1, t_2]) \leq \mu_X(t_1, t_2) \ln \left( \frac{h_Y^X(t_1, t_2)}{h_X^Y(t_1, t_2)} \right).
\]

**Proof:** Under the given condition, \( f(x)/g(x) \) is increasing in \( x > 0 \). Then for \( t_1 < x < t_2 \), we have \( \frac{f(t_1)}{g(t_1)} \leq \frac{f(x)}{g(x)} \leq \frac{f(t_2)}{g(t_2)} \). Thus from (1.4) we obtain

\[
D_{KL}^w(X[Y; t_1, t_2]) \leq \int_{t_1}^{t_2} x \frac{f(x)}{\Delta F} \ln \left( \frac{f(t_2)/\Delta F}{g(t_2)/\Delta G} \right) dx
\]

(5.3)

\[
= \mu_X(t_1, t_2) \ln \left( \frac{h_X^X(t_1, t_2)}{h_Y^X(t_1, t_2)} \right)
\]

and

\[
D_{KL}^w(X[Y; t_1, t_2]) \geq \int_{t_1}^{t_2} x \frac{f(x)}{\Delta F} \ln \left( \frac{f(t_1)/\Delta F}{g(t_1)/\Delta G} \right) dx
\]

(5.4)

\[
= \mu_X(t_1, t_2) \ln \left( \frac{h_Y^X(t_1, t_2)}{h_X^Y(t_1, t_2)} \right).
\]

Combining (5.3) and (5.4), we obtain the required inequalities.
**Proposition 5.5.** Let $X$ and $Y$ be two random variables as described in Proposition 5.1. Then

$$D_{KL}^w(X||Y; t_1, t_2) \geq \mu_X(t_1, t_2) \ln \left( \frac{\mu_X(t_1, t_2)}{\mu_Y(t_1, t_2)} \right).$$

**Proof:** The result follows from the log-sum inequality and hence omitted.

**Proposition 5.6.** Let $X$ and $Y$ be two random variables as described in Proposition 5.1. Then

\begin{equation}
(5.5) \quad D_{KL}^w(X||Y; t_1, t_2) \leq E \left( X \frac{f(X)/\Delta F}{g(X)/\Delta G} \bigg| t_1 < X < t_2 \right) - \mu_X(t_1, t_2).
\end{equation}

**Proof:** The proof follows from the inequality \( \ln x \leq x - 1 \), for all \( x > 0 \). Hence it is omitted.

Hereafter, we consider three nonnegative random variables $X_1$, $X_2$ and $X_3$ and obtain bounds of $D_{KL}^w(X_1||X_3; t_1, t_2)$, $D_{KL}^w(X_1||X_2; t_1, t_2)$ and $D_{KL}^w(X_2||X_3; t_1, t_2)$.

**Proposition 5.7.** Let $X_1$, $X_2$ and $X_3$ be three nonnegative absolutely continuous random variables with pdf's $f_1(x)$, $f_2(x)$ and $f_3(x)$, respectively. The corresponding cdf's are $F_1(x)$, $F_2(x)$ and $F_3(x)$. If $X_1 \geq^{tr} X_2$, then

$$D_{KL}^w(X_1||X_3; t_1, t_2) \geq \mu_{X_1}(t_1, t_2) \ln \left( \frac{h_{X_1}^{t_1}(t_1, t_2)}{h_{X_3}^{t_1}(t_1, t_2)} \right) + ID^w(t_1, t_2)$$

and

$$D_{KL}^w(X_1||X_2; t_1, t_2) \leq \mu_{X_1}(t_1, t_2) \ln \left( \frac{h_{X_1}^{t_1}(t_1, t_2)}{h_{X_2}^{t_1}(t_1, t_2)} \right) + ID^w(t_1, t_2),$$

where $ID^w(t_1, t_2) = I^w(X_1||X_3; t_1, t_2) - I^w(X_1||X_2; t_1, t_2)$.

**Proof:** Using $X_1 \geq^{tr} X_2$ and $t_1 < x$, we obtain $f_1(x) \geq f_2(x)f_1(t_1)/f_2(t_1)$. Thus, from (1.4)

\begin{equation}
(5.6) \quad D_{KL}^w(X_1||X_3; t_1, t_2) = \int_{t_1}^{t_2} f_1(x) \frac{\Delta F_1}{\Delta F_3} \ln \left( \frac{f_1(x)/\Delta F_1}{f_3(x)/\Delta F_3} \right) dx
\geq \int_{t_1}^{t_2} f_1(x) \frac{\Delta F_1}{\Delta F_3} \ln \left( \frac{(f_2(x)f_1(t_1))/(\Delta F_2\Delta F_1)}{(f_3(x)f_2(t_1))/(\Delta F_3\Delta F_2)} \right) dx
= \mu_{X_1}(t_1, t_2) \ln \left( \frac{h_{X_1}^{t_1}(t_1, t_2)}{h_{X_2}^{t_1}(t_1, t_2)} \right) + ID^w(t_1, t_2).
\end{equation}

The upper bound can be obtained similarly. This completes the proof.
Proposition 5.8. Let $X_1$, $X_2$ and $X_3$ be three random variables as described in Proposition 5.7. If $X_2 \geq_{lr} X_3$, then

$$D_{KL}^w(X_1||X_2; t_1, t_2) \geq \mu_{X_1}(t_1, t_2) \ln \left( \frac{h_{X_1}^2(t_1, t_2)}{h_{X_2}^2(t_1, t_2)} \right) + IS_1^w(t_1, t_2)$$

and

$$D_{KL}^w(X_1||X_2; t_1, t_2) \leq \mu_{X_1}(t_1, t_2) \ln \left( \frac{h_{X_1}^2(t_1, t_2)}{h_{X_2}^2(t_1, t_2)} \right) + IS_1^w(t_1, t_2),$$

where $IS_1^w(t_1, t_2) = h_{X_1}(X_1||X_3; t_1, t_2) - S^w(X_1; t_1, t_2)$.

Proof: Under $X_2 \geq_{lr} X_3$, for $x < t_2$, we have $f_2(x) \leq f_3(x)f_2(t_2)/f_3(t_2)$. Thus applying this inequality in (1.4) and after some simplifications, lower bound can be obtained. The upper bound can be obtained similarly. This completes the proof. \qed

Proposition 5.9. Let $X_1$, $X_2$ and $X_3$ be three random variables as described in Proposition 5.7. If $X_1 \geq_{lr} X_3$, then

$$D_{KL}^w(X_2||X_3; t_1, t_2) \geq \mu_{X_2}(t_1, t_2) \ln \left( \frac{h_{X_2}^2(t_1, t_2)}{h_{X_1}^2(t_1, t_2)} \right) + IS_2^w(t_1, t_2)$$

and

$$D_{KL}^w(X_2||X_3; t_1, t_2) \leq \mu_{X_2}(t_1, t_2) \ln \left( \frac{h_{X_2}^2(t_1, t_2)}{h_{X_1}^2(t_1, t_2)} \right) + IS_2^w(t_1, t_2),$$

where $IS_2^w(t_1, t_2) = h_{X_2}(X_2||X_1; t_1, t_2) - S^w(X_2; t_1, t_2)$.

Proof: It is given that $X_1 \geq_{lr} X_3$. Therefore, for $x > t_1$, we have $f_3(x) \leq f_1(x)f_3(t_1)/f_1(t_1)$. Applying this in (1.4), we get the lower bound of $D_{KL}^w(X_2||X_3; t_1, t_2)$. The upper bound can be obtained similarly. This completes the proof. \qed

6. NUMERICAL EXAMPLES

In this section, we consider examples for the verification of few of the results obtained in Section 5. To verify the Proposition 5.2, we consider the following example and present numerical values of the lower and upper bounds of the doubly truncated weighted KLD.

Example 6.1. Suppose that $X$ follows power distribution and $Y$ follows U-quadratic distribution in the interval $(0, 1)$ with pdfs $f(x) = cx^{c-1}$, $c > 0$, $0 < x < 1$ and $g(x) = 12(x - \frac{1}{2})^2$, $0 < x < 1$, respectively. Here, $f(x)$ is decreasing in $x$ for $c < 1$ and increasing in $x$ for $c > 1$. In Table 1 and Table 2, we present numerical values of the lower bounds (LB) and upper bounds (UB) of the doubly truncated weighted KLD for different values of $t_1$ and $t_2$ for $c = 0.5$ and $1.5$, respectively.
we present the numerical values of the bounds of the doubly truncated weighted KLD for \( b = 0.2 \) and \( b = 1.2 \), respectively.

**Table 3:** Bounds of \( D_{KL}^{w}(X||Y; t_1, t_2) \) for \( b = 0.2 \).

| \((t_1, t_2)\) | LB \( D_{KL}^{w}(X||Y; t_1, t_2) \) | UB \( D_{KL}^{w}(X||Y; t_1, t_2) \) |
|---------------|-----------------|-----------------|
| (0.1,0.4)     | −0.042188       | 0.006974        |
| (0.1,0.5)     | −0.074668       | 0.012759        |
| (0.1,0.9)     | −0.532245       | 0.044619        |
| (0.2,0.5)     | −0.068887       | 0.007283        |
| (0.2,0.7)     | −0.193724       | −0.020447       |
| (0.2,0.8)     | −0.315074       | −0.027845       |

**Table 4:** Bounds of \( D_{KL}^{w}(X||Y; t_1, t_2) \) for \( b = 1.2 \).

| \((t_1, t_2)\) | LB \( D_{KL}^{w}(X||Y; t_1, t_2) \) | UB \( D_{KL}^{w}(X||Y; t_1, t_2) \) |
|---------------|-----------------|-----------------|
| (0.1,0.4)     | −0.090386       | 0.020384        |
| (0.1,0.5)     | −0.015747       | 0.004043        |
| (0.1,0.9)     | −0.069415       | 0.028401        |
| (0.2,0.5)     | −0.015039       | 0.002460        |
| (0.2,0.7)     | −0.036351       | 0.008604        |
| (0.2,0.8)     | −0.052349       | 0.014472        |

To illustrate Proposition 5.3, we consider the following example.

**Example 6.2.** Let \( X \) and \( Y \) be two random variables with pdfs \( f(x) = 1, \ 0 < x < 1 \) and \( g(x) = b(1 - x)^{b-1}, \ 0 < x < 1, b > 0 \), respectively. Note that \( g(x) \) is increasing in \( x \) for \( b < 1 \) and decreasing in \( x \) for \( b > 1 \). In Table 3 and 4, we present the numerical values of the bounds of the doubly truncated weighted KLD for \( b = 0.2 \) and \( b = 1.2 \), respectively.
The following example shows a case in which Proposition 5.4 is fulfilled.

**Example 6.3.** Consider two nonnegative random variables $X$ and $Y$ with pdfs $f(x) = \frac{3}{4}(1 + x)$, $0 < x < 1$ and $g(x) = \frac{3}{4}(2 - x)$, $0 < x < 1$, respectively. By straightforward calculations, it is not hard to verify that $X \geq_{lr} Y$. In Table 5, we present the numerical values of the lower and upper bounds of the doubly truncated weighted KLD between $X$ and $Y$.

**Table 5:** Bounds of $D_{X|Y}^{W}(t_1, t_2)$.

| $(t_1, t_2)$ | LB $D_{KL}(X||Y; t_1, t_2)$ | UB $D_{KL}(X||Y; t_1, t_2)$ | $(t_1, t_2)$ | LB $D_{KL}(X||Y; t_1, t_2)$ | UB $D_{KL}(X||Y; t_1, t_2)$ |
|-------------|-----------------------------|-----------------------------|-------------|-----------------------------|-----------------------------|
| (0.1,0.3)   | -0.028607                   | 0.005274                    | (0.5,0.7)   | -0.980397                   | 0.006264                    |
| (0.1,0.6)   | -0.126393                   | 0.034815                    | (0.5,0.8)   | -0.131348                   | 0.014560                    |
| (0.1,0.8)   | -0.229447                   | 0.071593                    | (0.5,0.9)   | -0.189889                   | 0.026835                    |
| (0.3,0.7)   | -0.023699                   | 0.001387                    | (0.6,0.7)   | -0.043674                   | 0.001614                    |
| (0.3,0.9)   | -0.248611                   | 0.056871                    | (0.6,0.9)   | -0.150375                   | 0.015624                    |

In this part of the paper, we provide an example in support of the Proposition 5.7.

**Example 6.4.** Let $X$ and $Y$ be two nonnegative random variables as described in Example 6.3. Consider another random variable $Z$ with pdf $f_3(x) = \frac{1}{2\sqrt{1-x}}$, $0 < x < 1$. Here, $X \geq_{lr} Y$. The lower and upper bounds of $D_{KL}(X||Y; t_1, t_2)$ obtained in the Proposition 5.7 are presented in Table 6.

**Table 6:** Bounds of $D_{KL}(X||Y; t_1, t_2)$.

| $(t_1, t_2)$ | LB $D_{KL}(X||Y; t_1, t_2)$ | UB $D_{KL}(X||Y; t_1, t_2)$ | $(t_1, t_2)$ | LB $D_{KL}(X||Y; t_1, t_2)$ | UB $D_{KL}(X||Y; t_1, t_2)$ |
|-------------|-----------------------------|-----------------------------|-------------|-----------------------------|-----------------------------|
| (0.1,0.2)   | -0.011750                   | 0.000238                    | (0.4,0.6)   | -0.074033                   | -0.001039                   |
| (0.1,0.5)   | -0.107631                   | 0.000543                    | (0.4,0.7)   | -0.127975                   | -0.003167                   |
| (0.1,0.7)   | -0.230205                   | -0.004876                   | (0.4,0.9)   | -0.274740                   | -0.012652                   |

**Real Data:** We consider two real data sets, which represent the failure times of the air conditioning system of two different air planes (see Bain and Engelhardt, 1991, p. 101). The data sets are given below:

**Data Set I** (Plane 7912): 1, 3, 5, 7, 11, 11, 11, 12, 14, 14, 14, 16, 16, 20, 21, 23, 42, 47, 52, 62, 71, 71, 87, 90, 95, 120, 120, 225, 246, 261.

**Data Set II** (Plane 7911): 33, 47, 55, 56, 104, 176, 182, 220, 239, 246, 320.
The above data sets, Data Set I and Data Set II can be fitted as exponential distributions with parameters (hazard rates) $\lambda_1$ and $\lambda_2$, respectively. We assume that due to some reasons, the data in the interval $[50, 200]$ are observed. Based on this assumption, the unknown parameters can be estimated. For this purpose, we use the method of maximum likelihood. Here, the estimated values of the parameters are $\hat{\lambda}_1 = 0.026029$ and $\hat{\lambda}_2 = 0.005611$. From (1.4), we get $\hat{D}_{KL}^w(X||Y; 50, 200) = 2.5069$.

7. CONCLUDING REMARKS

In this paper, we consider a generalized discrimination measure, which is known as the doubly truncated weighted KLD. We obtain few characterization results based on the proposed measure. These results may be useful in studying various characteristics of a system when its lifetimes fall in an interval. Further, the effect of the affine transformations on the proposed discrimination measure is studied. Several inequalities and bounds are obtained. Finally, few applications with bounds in support of the results are presented.
